Lecture 5

So far…

$$s = f(x; W) = Wx$$

Score function

$$L_i = -\log\left(\frac{e^{s_{y_i}}}{\sum_j e^{s_j}}\right)$$

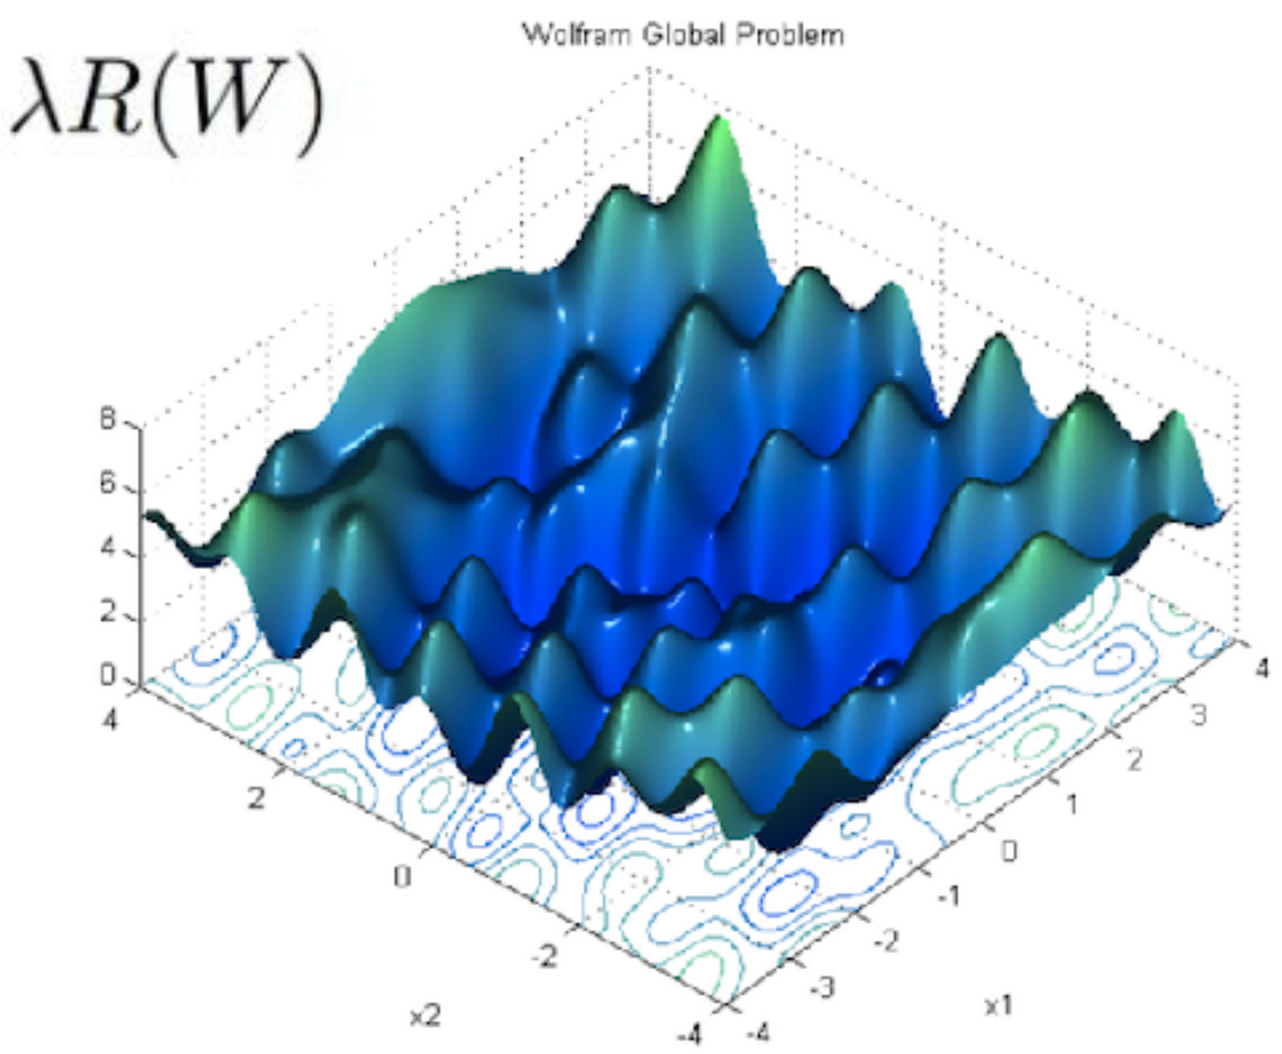
$$L_i = \sum_{j \neq y_i} \max(0, s_j - s_{y_i} + 1)$$

Loss per data point

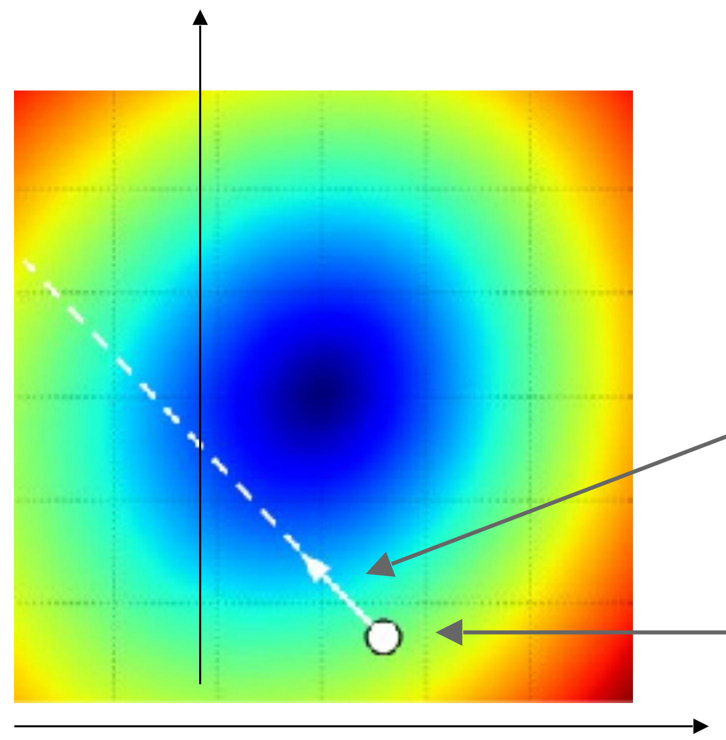
$$L(W) = \frac{1}{N} \sum_{i=1}^{N} L_i(x_i, y_i, W) + \lambda R(W)$$

Average loss over data
+ regularization

$$L(W) = \frac{1}{N} \sum_{i=1}^{N} L_i(x_i, y_i, W) + \lambda R(W)$$



Loss surface (lots of local minima)



$$W_{t+1} = W_t - \lambda \nabla_W L(W_t)$$

Gradient descent

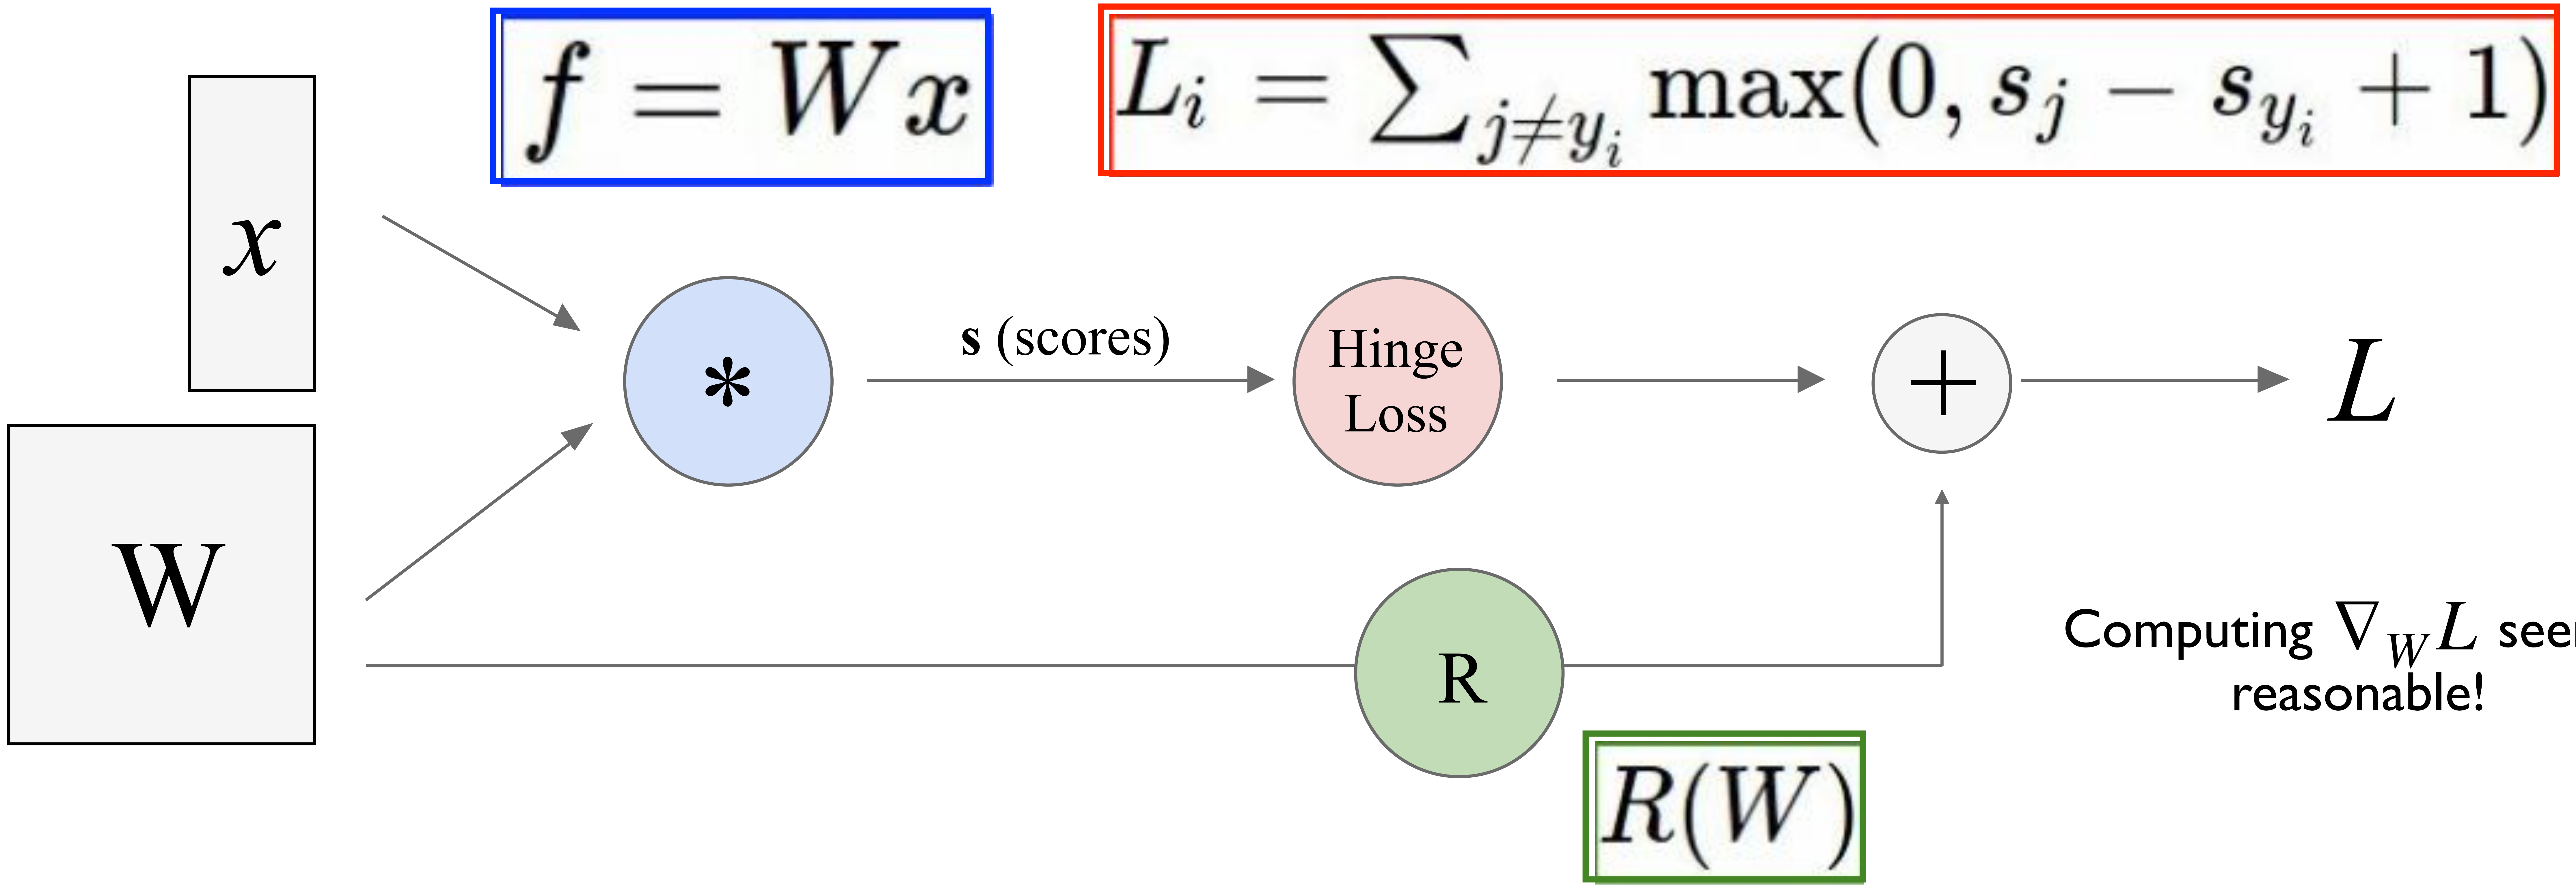
$$\nabla_W L(W) = \frac{1}{N} \sum_{i=1}^{N} \nabla_W L_i(x_i, y_i, W) + \lambda \nabla_W R(W)$$

$$\nabla_W L(W) \approx \frac{1}{|B|} \sum_{(x,y) \in B} \nabla_W L(x, y, W) + \lambda \nabla_W R(W)$$

Stochastic gradient descent
(minibatch sampling)

Just add gradients…

Computational graphs



Computing $\nabla_W L$ seems reasonable!

Backpropagation

The chain rule of derivatives

How does the output of
our function *f* change

It changes as *g* changes…

$$\frac{\partial f}{\partial x} = \frac{\partial f}{\partial g}\frac{\partial g}{\partial x}$$

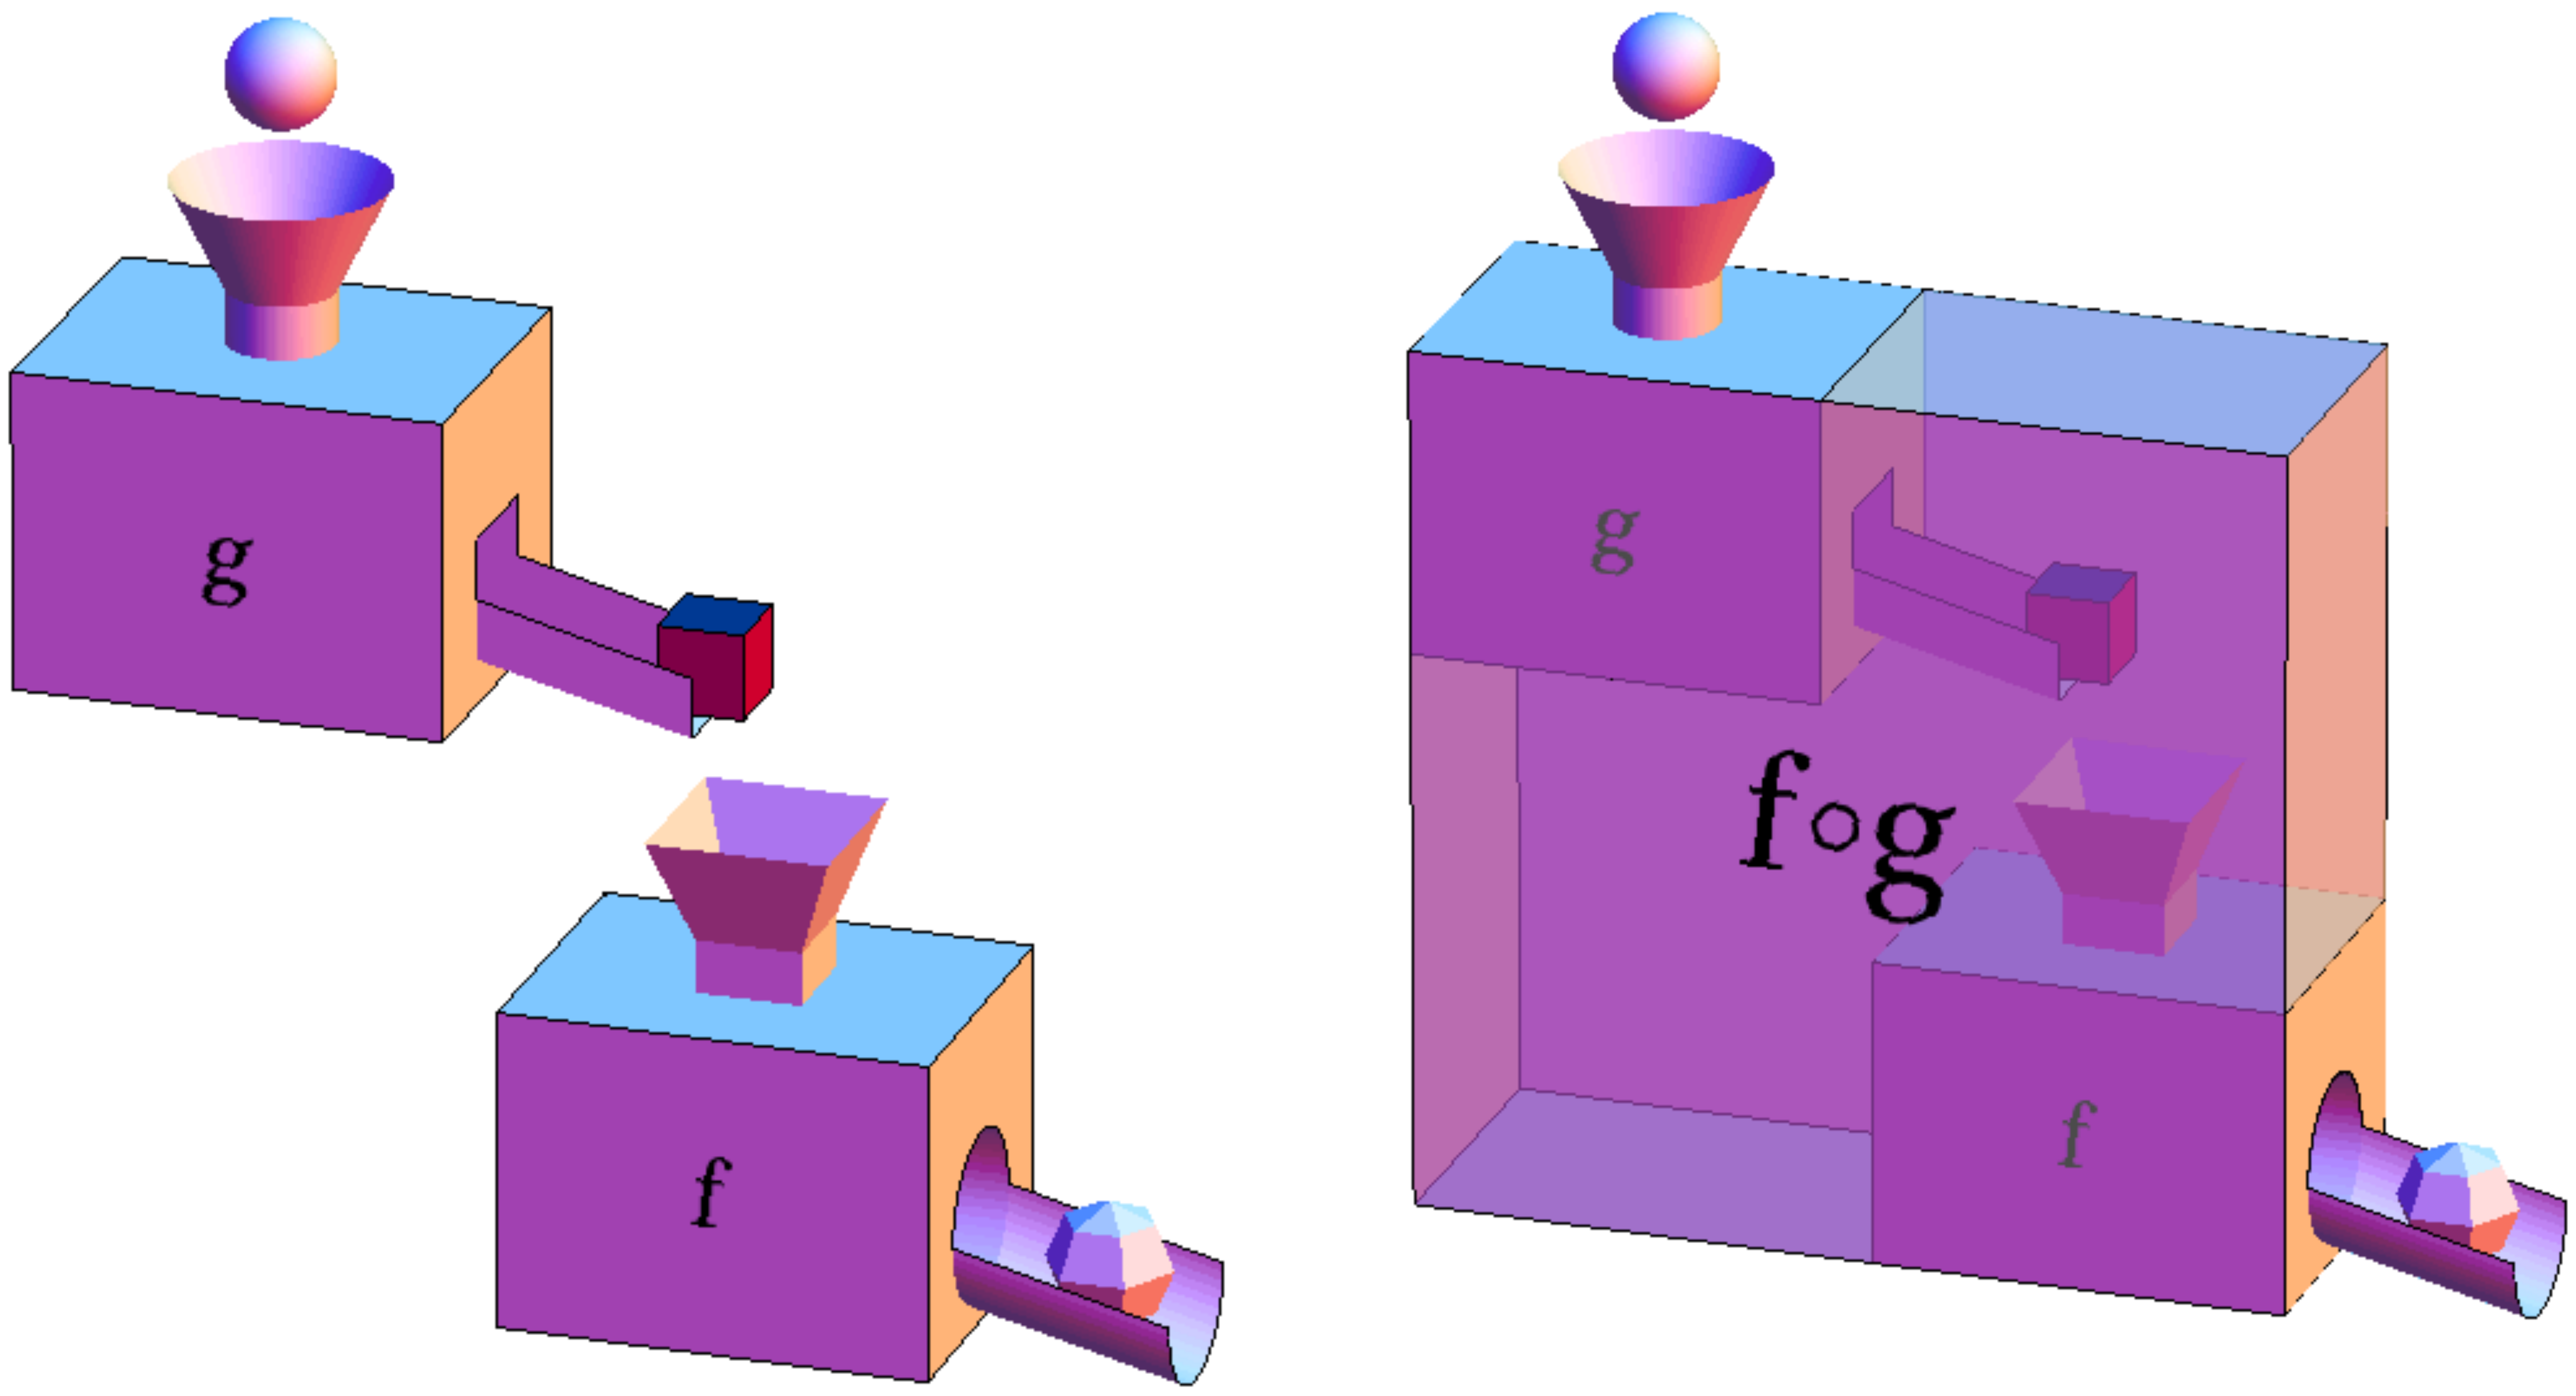
As we tweak the input *x*?

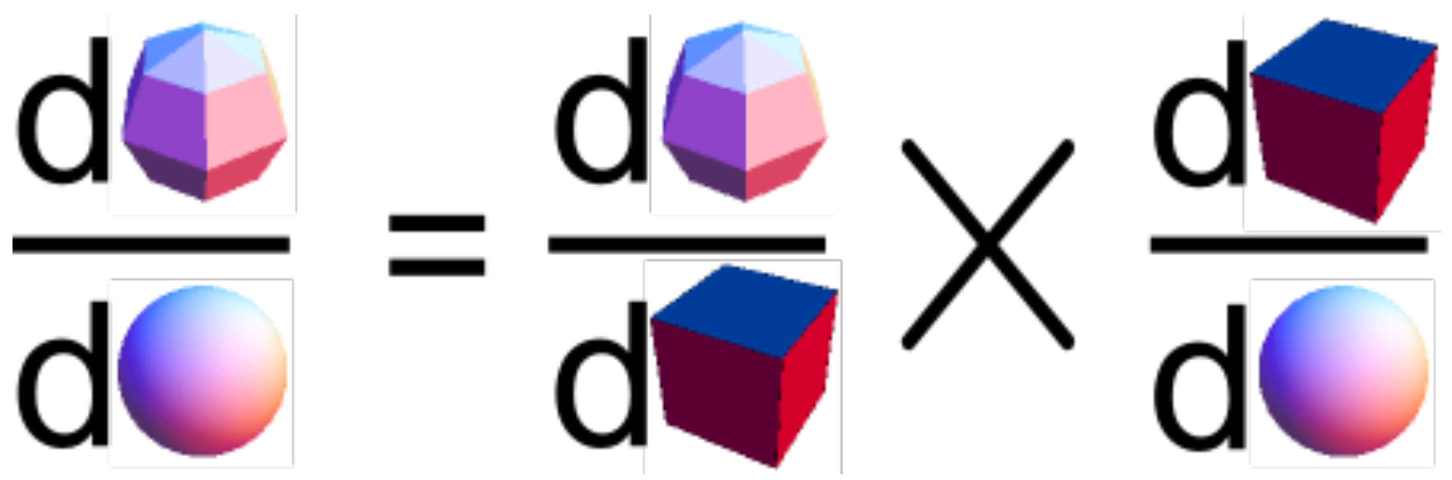
…which changes as *x* changes.

$$(f \circ g)(x) = f(g(x))$$

Used with permission from David Wingate

The chain rule of derivatives





$$(f \circ g)(x) = f(g(x))$$

$$\frac{\partial f}{\partial x} = \frac{\partial f}{\partial g}\frac{\partial g}{\partial x}$$

More generally

$$g : \mathbb{R}^m \to \mathbb{R}^n \qquad y = g(x)$$

$$f : \mathbb{R}^n \to \mathbb{R} \qquad z = f(y)$$

The chain rule must sum over all "paths" between z and x!

$$\frac{\partial z}{\partial x_i} = \sum_j \frac{\partial z}{\partial y_j} \frac{\partial y_j}{\partial x_i}$$

$$\nabla_{\boldsymbol{x}} z = \left(\frac{\partial \boldsymbol{y}}{\partial \boldsymbol{x}} \right)^\top \nabla_{\boldsymbol{y}} z.$$

Automatic differentiation

Automatic differentiation is the algorithmic application

of the **identities of derivatives**

to **computation graphs**

(either defined via an API, or direct source code analysis)

It is not symbolic differentiation (ala Maple), or numerical differentiation

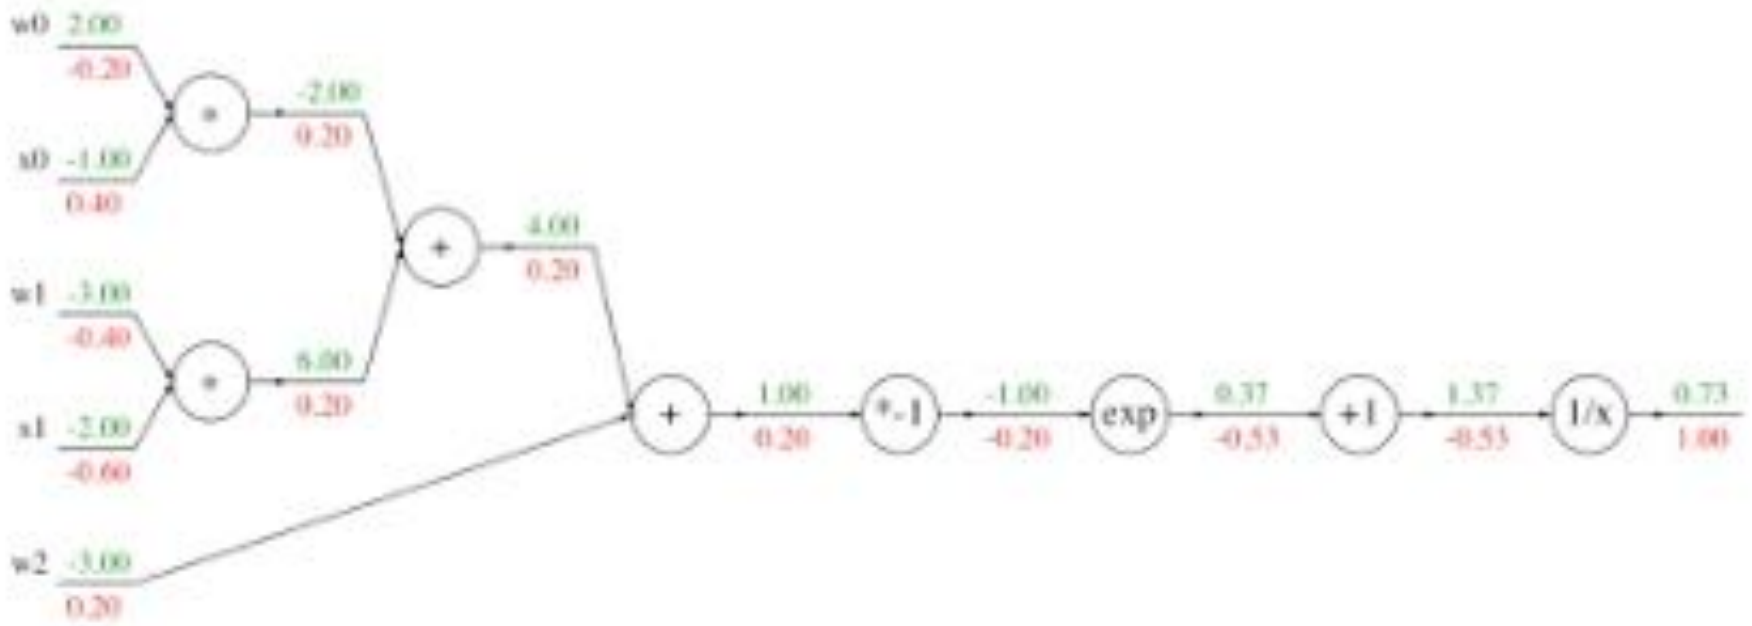
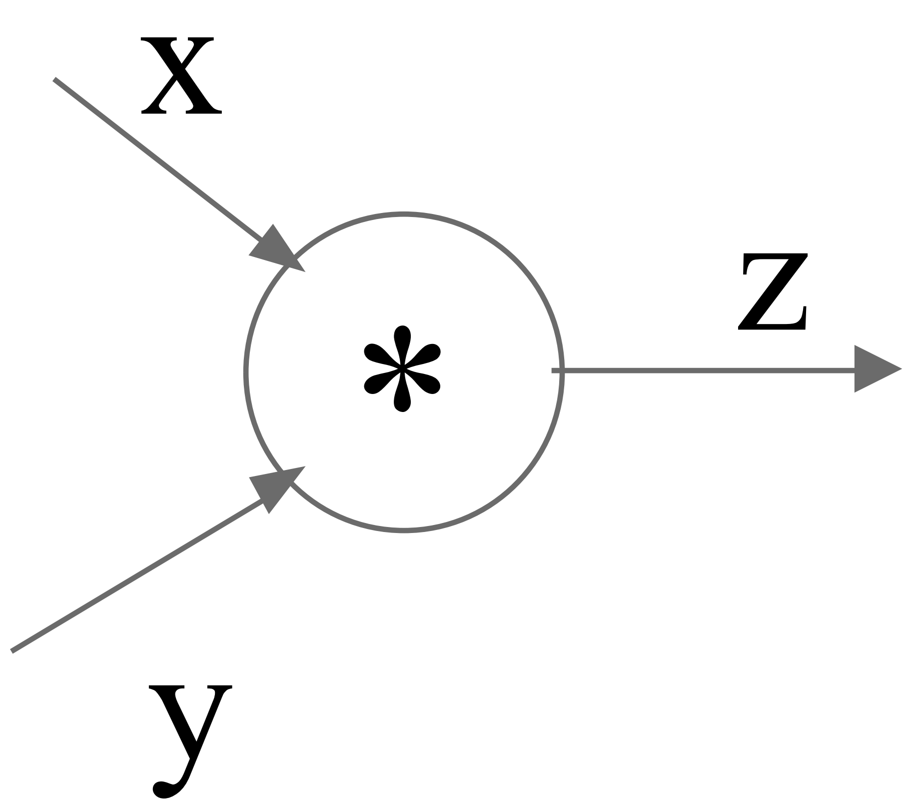
Modularized implementation: forward / backward API



Graph (or Net) object *(rough pseudo code)*

```
class ComputationalGraph(object):
    #...
    def forward(inputs):
        # 1. [pass inputs to input gates...]
        # 2. forward the computational graph:
        for gate in self.graph.nodes_topologically_sorted():
            gate.forward()
        return loss # the final gate in the graph outputs the loss
    def backward():
        for gate in reversed(self.graph.nodes_topologically_sorted()):
            gate.backward() # little piece of backprop (chain rule applied)
        return inputs_gradients
```

Modularized implementation: forward / backward API



(x,y,z are scalars)

```
class MultiplyGate(object):
    def forward(x,y):
        z = x*y
        self.x = x # must keep these around!
        self.y = y
        return z
    def backward(dz):
        dx = self.y * dz # [dz/dx * dL/dz]
        dy = self.x * dz # [dz/dy * dL/dz]
        return [dx, dy]
```

This is what Tensorflow/PyTorch/Keras (etc) is for!

Classes

- `class AveragePooling1D` : Average Pooling layer for 1D inputs.
- `class AveragePooling2D` : Average pooling layer for 2D inputs (e.g. images).
- `class AveragePooling3D` : Average pooling layer for 3D inputs (e.g. volumes).
- `class BatchNormalization` : Batch Normalization layer from http://arxiv.org/abs/1502.03167.
- `class Conv1D` : 1D convolution layer (e.g. temporal convolution).
- `class Conv2D` : 2D convolution layer (e.g. spatial convolution over images).
- `class Conv2DTranspose` : Transposed 2D convolution layer (sometimes called 2D Deconvolution).
- `class Conv3D` : 3D convolution layer (e.g. spatial convolution over volumes).
- `class Conv3DTranspose` : Transposed 3D convolution layer (sometimes called 3D Deconvolution).
- `class Dense` : Densely-connected layer class.
- `class Dropout` : Applies Dropout to the input.
- `class Flatten` : Flattens an input tensor while preserving the batch axis (axis 0).
- `class InputSpec` : Specifies the ndim, dtype and shape of every input to a layer.
- `class Layer` : Base layer class.
- `class MaxPooling1D` : Max Pooling layer for 1D inputs.
- `class MaxPooling2D` : Max pooling layer for 2D inputs (e.g. images).
- `class MaxPooling3D` : Max pooling layer for 3D inputs (e.g. volumes).
- `class SeparableConv1D` : Depthwise separable 1D convolution.
- `class SeparableConv2D` : Depthwise separable 2D convolution.

In Assignment 1: Writing SVM / Softmax

Stage your forward/backward computation!

E.g. for the SVM:

```
# receive W (weights), X (data)
# forward pass (we have 8 lines)
scores = #...
margins = #...
data_loss = #...
reg_loss = #...
loss = data_loss + reg_loss
# backward pass (we have 5 lines)
dmargins = # ... (optionally, we go direct to dscores)
dscores = #...
dW = #...
```

Summary so far...

- neural nets will be very large: impractical to write down gradient formula by hand for all parameters
- **backpropagation** = recursive application of the chain rule along a computational graph to compute the gradients of all inputs/parameters/intermediates
- implementations maintain a graph structure, where the nodes implement the **forward** () / **backward** () API
- **forward** : compute result of an operation and save any intermediates needed for gradient computation in memory
- **backward** : apply the chain rule to compute the gradient of the loss function with respect to the inputs
